👥 Roles:

1. **Farmer (Ravi)** – hardworking, worried about crop health
2. **Agriculture Officer (Mr. Kumar)** – experienced but limited by manual diagnosis
3. **Student 1 (Shiva)** – tech-savvy developer (you can play this role)
4. **Student 2 (Shreyan)** – main presenter/narrator who transitions to the explanation

---

🌾 Scene 1: A Farmer's Struggle (Field – Morning)

(Soft ambient farm sounds — birds, wind. Farmer walks through his field, inspecting leaves.)

Farmer (worried):
"These leaves are turning yellow again… and these brown spots keep spreading. I sprayed what the shopkeeper suggested last week, but it's only getting worse…"

(He plucks a leaf, sighs, and wipes sweat)
Farmer:
"If I lose another season, I don't know how I'll manage my loan."

(Agriculture Officer enters holding clipboard)

Officer:
"Good morning, Ravi. Still having trouble with your crops?"

Farmer:
"Yes sir… I think it's that same disease from last year. But no one's sure what it is. They say its some bacterial Disease"

Officer:
"Hmmm… (examines leaf) Hard to tell. We'd need a lab test to confirm. But that'll take at least a week."

Farmer (frustrated):
"A week? By then half my field might dry up!"

(Both look helpless. Pause — dramatic music starts softly.)

Scene 2:

Shiva:
"You know, I was reading about how farmers often misidentify plant diseases because symptoms look similar. It costs them weeks of time and thousands in losses."

Shreyan:
"Exactly. What if we could use **AI** to do what lab tests do — instantly?
Just a photo, and the system tells you the disease and how to treat it."

Shiva (excited):
"Yes! Like using image recognition —we could identify the diseases and inform the farmers at an early stage."

(They exchange determined looks)

Shreyan:
"Let's do it. For farmers like Ravi."

(Cut back to field scene)

(process of making of our project)

Farmer (checking phone):
"Oh, what's this app? 'Crop Disease Identifier'? Maybe I should try…"

(He clicks a picture of his leaf. After a moment, screen flashes result.)

"Diagnosis: Rice Leaf Blast. Suggested Treatment: Apply tricyclazole 0.06% and avoid excess nitrogen fertilizer."

(Farmer smiles in relief)
Farmer:
"This… this actually works!"

(Officer looks surprised)
Officer:
"Who made this?"

(Cut to students entering scene proudly)

Shiva:
"We did."
(camera pans up dramatically, transition to next scene)

🎬 Scene 3

🧠 Team Leader / Producer (Opening the Scene)

(Calm, confident tone)

“Good morning everyone.
We are Team Cropify, and I am Shreyan, The Project leader, today we’re excited to present our project — Crop Disease Identifier.

Our idea began with a simple question: *What if farmers could detect crop diseases instantly, right from their phone or laptop?*
This project is an AI-powered tool that analyzes leaf images to quickly and accurately identify crop diseases, helping farmers take timely action and reduce crop losses.

Our goal was simple — to create an AI-powered solution that could quickly and accurately identify crop diseases just by analyzing leaf images.
We designed every step carefully, from collecting high-quality data to building an intelligent model and finally developing a clean and user-friendly interface.”

,

📊 Data Expert (About Dataset Collection & Preparation)

(Explains with slight enthusiasm)

> **Hi i am Akshath i am the data expert**
>
> “To make our AI accurate, we first needed the right data.
> We collected large, high-quality image datasets for **Rice**, **Wheat**, **Tomato**, and **Cotton** from **Kaggle**.
> Each dataset contained images of healthy and diseased leaves across different categories — over **40 disease and pest classes** in total.
>
> For training, we used **Google Colaboratory** for the Rice and Wheat models, while the **Tomato and Cotton** datasets were trained using **Google Teachable Machine**, which allowed us to quickly build image classifiers through transfer learning.
>
> All the datasets were then cleaned, resized, and normalized before training — ensuring that the model learned efficiently from high-quality, consistent data.”
>
> Now lets see the product

🎬 Video Editor & Tester (About Functionality, Features, and User Experience)

Hi i am adarsh, the video producer and tester of our project

—------not to be said—--

1️⃣ The user selects the crop type and uploads a leaf image.
2️⃣ The image is preprocessed — resized and normalized for accurate prediction.
3️⃣ The correct AI model (TFLite) is loaded automatically based on the selected crop.
4️⃣ The model predicts the disease and gives a confidence score.
5️⃣ The app displays the disease name, cause, and suggested recovery methods immediately.

—----------

Coder:

Hi i am shiva, the coder and ui developer

Technically, we built the backend using Python and TensorFlow/Keras. libraries
The interface uses Flask combined with HTML and Bootstrap 5, giving it a clean, responsive design.
To make it run as a desktop app, we used PyWebView, which removes the need for a browser and provides a native-app experience.

🧠 Team Leader / Producer (Closing the Scene)

“Through this project, we wanted to bring **AI directly into the hands of farmers** — making disease detection faster, simpler, and more reliable.
By reducing crop losses and promoting timely action, our **Crop Disease Identifier** takes one step closer to **smarter, sustainable agriculture**.

In the future, we aim to expand this system by adding **more crop varieties**, integrating **voice-based assistance in local languages**, and even developing a **mobile app version** for easier field use.

We also plan to include **real-time weather-based disease prediction** and a **community support feature** where farmers can share results and get expert feedback instantly.

Our vision is to make technology not just advanced — but truly accessible to every farmer, everywhere.”
